

COBRO IMS

Client System Walkthrough

Presenter's Script & Demonstration Guide

This document is built from the current, live Cobro IMS application — every screen, button, status and report named here was independently re-verified against the actual application source code before this corrected version was produced.

For internal presenter use only — not for distribution to the client.

Corrected edition — see the change notes at the top of the file that generated this PDF for exactly what was fixed and why.

How to Use This Document

This script is written so you can read the plain paragraphs aloud, almost word for word, while you actually operate the system. The coloured boxes are instructions for you — they are not part of what you say to the client, except where a box itself contains a suggested sentence (marked clearly).

Plain paragraphs — read these aloud, in your own natural voice.

Lines starting with "ACTION:" — things to click, type or do. Do not read these aloud.

Lines starting with "PRESENTER NOTE:" — background context for you only.

The five navigation markers used throughout:

Marker	Meaning
[NAVIGATE]	You are about to move to a different screen or page in the system.
[DEMONSTRATE]	You are about to actually click, type, scan or submit something.
[EXPLAIN]	A spoken explanation with no action — just talk the audience through a concept.
[ROLE SWITCH]	You are about to sign out and sign back in as a different user, because responsibility for the next step
[IMPORTANT / BACKUP]	A caution to keep in mind, or a ready-made fallback sentence if something on screen doesn't

PRESENTER NOTE: Everywhere this script names a specific product, it uses two placeholder names: "Steel Trowel" for an ordinary stock item, and "Concrete Pump Motor" for a repair item. These are suggested names only — see the Pre-Demo Checklist for exactly what to do with them before tomorrow. Wherever you see one of these two names in the script, simply say whatever you actually named your demo product instead.

Pre-Demo Checklist

Everything below should be confirmed or completed before you sit down with the client. None of it needs to be done live, and most of it takes only a few minutes.

1. Rename the demo products — highest priority

The two products currently set up in the system for testing are named “Regression Test Normal” and “Regression Test Repair”. *(Presenter: confirm these are still the actual names in your live system before tomorrow — this could not be independently verified against the live database from outside the application; see the pre-flight checklist at the end of this document.)* These are internal testing names and must not appear in front of the client. Before tomorrow, open Product catalogue as Admin and rename these two products to something presentable — for example “Steel Trowel” (an ordinary stock item) and “Concrete Pump Motor” (kept in the existing “Repair items” category). This is a simple name change on the existing product record — it does not affect the barcode, category, stock levels, or any of the requisition/transfer history already built up against them, so the rest of this script stays accurate. This script uses those two example names throughout — if you choose different names, just substitute your own wherever the script names a product.

2. Confirm your demo accounts

An Admin account, ready to use, for the Product Catalogue, approving requisitions, Receiving, Reports, Audit Log and Users sections.

A second **Admin** account with 2FA already enrolled and working, kept specifically for the Adjustments **approval** step — approving an adjustment requires a verified second-factor code, so this needs to be tested and ready, not set up on the day. **This must be an Admin account, not Stores Manager: in the current system, only Admin holds the permission to approve an adjustment. A Stores Manager can raise an adjustment but the Approve action itself is not available to that role, 2FA or not.**

An Engineer / Requester account, ready to use — this is the account that owns a personal station, and is what lets you show Scan-to-Use, self-accepting a requisition, and Return to Stores.

If you intend to also show a Stores Manager, Stores Clerk, Supervisor or Team Leader account, confirm a working login exists for it and that it is not stuck on a temporary first-login password. The core script below only requires the two accounts above; it marks clearly where one of these other roles could be substituted in if you have one ready.

3. Confirm the demo product’s stock position

Both demo products have a barcode assigned (needed for the scanning steps).

There is a real, non-zero quantity on hand in the main store for both, so the requisition demonstration has genuine stock to reserve.

The reorder point is set at a level that suits what you want to show — below current stock if you don’t want a “below reorder point” warning showing on the Dashboard, or above it if you specifically want to demonstrate that warning.

4. Leave the existing transaction history in place

There is already a short, genuine history of requisitions and transfers against the repair-item product from earlier testing. You do not need to erase this or start from zero — it is exactly what will make the Reports and history sections look populated and credible rather than empty. Build the live parts of your demonstration on top of it.

5. Purchase Orders (only if you plan to show this module specifically)

If you want to walk through the formal Purchase Order lifecycle (as opposed to the quick receiving option), have at least one supplier already set up under Suppliers, and ideally one Purchase Order already issued with a remaining outstanding quantity, so you can show a live receipt without building the whole order from scratch on stage.

6. Have your own authenticator app ready

If your day-to-day account uses 2FA, or you're using the dedicated 2FA account for the Adjustments step, have the authenticator app open on your phone before you start, so you are not searching for it live.

7. Close other sessions

Make sure no other browser tab or window is signed in as a different Cobro user, so you never accidentally present from the wrong account.

Live Demo Safety Guide

Every action below is real — nothing in Cobro IMS is a simulated demo mode. This table tells you, honestly, which actions are safe to perform freely in front of the client, which should be rehearsed once beforehand, and which should be avoided unless specifically asked for.

Action	What actually happens	Recommendation
Receiving stock (quick receive)	Permanently increases stock on hand.	Safe to do live, freely.
Creating a requisition (draft)	No stock effect until approved.	Safe to do live, freely.
Approving a requisition	Reserves real stock against that request.	Safe to do live, freely.
Dispatching / issuing a requisition	Posts a real stock movement, moves stock to the requester's station.	Safe live — do it once per rehearsed sequence.
Engineer accepting their own requisition	Same effect as above.	Safe live.
Scan-to-Use	Permanently reduces stock; cannot be undone except by a separate adjustment.	Rehearse once beforehand; fine to repeat live, just be aware each scan really consumes stock.
Initiating a transfer	Immediately removes stock from the source location into an in-transit state.	Safe live — always complete the receiving side in the same segment so nothing is left stranded in transit.
Return to Stores	Removes stock from the Engineer's station into transit back to the store.	Safe live.
Requesting an adjustment	No stock effect until approved.	Safe live.
Approving/rejecting an adjustment	Permanently changes stock; requires a verified 2FA session; cannot be reversed except by another adjustment.	Rehearse this exact step beforehand with the 2FA-ready Admin account tested and working.
Changing a user's role or permissions	Affects a real account immediately.	Avoid live unless specifically asked; use a disposable test account if you do.
Deactivating a user	Immediately blocks that account from logging in.	Avoid live unless specifically asked, and only on a disposable test account.

Backup Plans

If any live step doesn't behave the way you expect — a slow network, a typo, a scanner that won't focus — you don't need to explain that anything has gone wrong. Each fallback below lets you say a completely natural sentence and pivot to something already on record that shows the same result.

Login is slow

[IMPORTANT / BACKUP] *"While that comes up, let's talk through what a user sees the moment they open the system."*

ACTION: *Keep describing the visible login fields (email, password, 'keep me signed in') while it loads.*

Receiving doesn't go as planned

[IMPORTANT / BACKUP] *"Rather than create a brand new receipt, let's look at one we already have on record, so you can see exactly the same result."*

ACTION: *Navigate to Dashboards & reports → Receiving history and point to an existing line.*

A new requisition doesn't behave as expected

[IMPORTANT / BACKUP] *"I can see this one is already sitting at exactly the stage we want, so let's continue from here instead."*

ACTION: *Use one of the existing requisitions already in the system rather than the one just created.*

Dispatch / acceptance doesn't complete cleanly

[IMPORTANT / BACKUP] *"This request has already been through exactly this step — let's look at what it looks like once it's been accepted."*

ACTION: *Point to an existing requisition already showing "Issued".*

A transfer doesn't complete

[IMPORTANT / BACKUP] *"Let's look at a transfer that's already been completed, so you can see the full journey in one view."*

ACTION: *Navigate to Transfers and point to an existing row marked "Completed".*

The camera scanner won't cooperate

[IMPORTANT / BACKUP] *"If the camera isn't playing along, the same result works by simply typing the barcode number in — the system treats it identically."*

ACTION: *Type the barcode digits into the scan field by hand instead of using the camera.*

The 2FA approval step stalls

[IMPORTANT / BACKUP] *"Rather than complete a live approval, let me show you an adjustment that's already been through this exact process, so you can see the full record of it."*

ACTION: *Navigate to Dashboards & reports → Adjustment reason summary, or the Audit log, and point to an already-approved adjustment.*

A report looks emptier than expected

[IMPORTANT / BACKUP] *“Let’s widen this slightly so you can see more of the picture.”*

ACTION: Clear or broaden any product/date filter on the report — reports are read-only, so there is no risk in experimenting with the filters live.

Role Relationship Overview

Cobro IMS has seven user roles. They are not seven separate, unrelated logins — they represent seven different responsibilities in the same, single stock process. This is worth understanding before the walkthrough, because the script below moves between roles exactly where responsibility genuinely changes hands.

Role	Their role in the process
Admin	Full oversight: manages the product catalogue, users, suppliers and pricing, and is the one who reviews the organisation's most sensitive actions, such as approving a stock adjustment. Admin does not raise requisitions — if Admin needs stock, that goes through a Purchase Order to a supplier instead.
Stores Manager	Runs the store side of the operation: purchase orders, receiving, transfers, and can raise (though not approve) a stock adjustment.
Stores Clerk	Day-to-day store operations — purchase orders, receiving and transfers, much like Stores Manager, but without the ability to raise an adjustment.
Engineer / Requester	The person out doing the work: raises a request for stock, works from their own personal holding location, can accept their own approved request, record stock as used, and return anything not needed.
Supervisor	Oversight across requisitions and reporting, without store-management responsibility.
Mechanical Team Leader	The same requisition and reporting oversight as a Supervisor, scoped to their own team.
Electrical Team Leader	The same requisition and reporting oversight as a Supervisor, scoped to their own team.

How responsibility actually moves through the system:

1. An Engineer / Requester raises a requisition for what they need.
2. An authorised Stores user (or Admin) reviews it and approves it — this reserves the stock.
3. The requisition is then dispatched — either by Stores, or by the Engineer themselves accepting their own approved request.
4. The stock arrives at the Engineer's own personal station.
5. The Engineer records it as used, or returns it to Stores if it isn't needed.
6. Every one of these steps is recorded automatically.
7. Reports and the Dashboard give Admin, Supervisors and Team Leaders visibility across all of it.

PRESENTER NOTE: This is the core story the whole presentation below is built around — every part of the script exists to demonstrate one link in this chain.

PRESENTER NOTE: The seven roles above, the two separate reporting chains they belong to, and the rule that Admin never raises a requisition, were all explicitly confirmed with Cobro. A handful of finer details — for instance, exactly what a Supervisor or Team Leader can do beyond viewing — are still open business decisions rather than finished, signed-off policy. If the client asks a very specific “can role X do Y” question that isn't covered by what's written above, it's fine to say that detail is still being confirmed with them, rather than guessing.

Anticipated Client Questions

Short, accurate, natural answers — grounded in what the system actually does.

“What happens if we don’t have enough stock?”

The system won’t let a request move forward if there isn’t enough available stock to reserve. If someone tries to approve a request for more than what’s actually available, it stops them and explains why, rather than letting the stock position go negative.

“Who approves a request?”

That depends on where the stock is coming from. If it’s coming from the main store, an authorised Stores user or Admin reviews and approves it. If it’s a request between two Engineers’ own stock, the Engineer who owns that stock approves it themselves.

“Can an Engineer request stock?”

Yes — that’s exactly how the process starts. An Engineer raises the request, and once it’s approved and issued, the stock lands on their own personal station.

“Where does the Engineer’s stock go?”

Every Engineer has their own personal holding location in the system — their station. Once stock is issued to them, it sits there until they either use it or return it.

“What happens if an Engineer doesn’t use an item?”

They can return it to Stores. That return is recorded as its own transaction, so the stock position stays accurate instead of stock simply sitting unused and untracked.

“Can stock be returned?”

Yes — exactly as above, from an Engineer’s station back to Stores.

“Can we see where stock is?”

Yes. The system always shows current stock by location — what’s in the store, and what’s currently held by each Engineer.

“How do we know who changed something?”

Every stock-affecting action is recorded with who did it and when. There’s a dedicated history for this, and it cannot be edited or deleted afterwards.

“Can everyone perform adjustments?”

No. Only specific roles can even raise an adjustment, and approving one — the step that actually changes stock — needs an extra layer of verification beyond a normal login, because it’s one of the most sensitive actions in the system.

“What happens when stock is transferred?”

It leaves the source location immediately and is shown as in transit — no longer available where it came from, but not yet added to the destination either — until the receiving side confirms it has arrived. That two-step process is what stops stock appearing to exist in two places at once.

“How do we know how much our stock is worth?”

There’s a dedicated valuation report that shows the value of everything currently held, based on the average cost of each item.

“How do we identify low stock?”

There’s a report built specifically for that — it shows anything that has dropped below the reorder point you’ve set for it.

“Can we scan items?”

Yes — barcodes can be used to look an item up, receive it in, issue it out, or record it as used, all from one scanning screen.

“What happens when someone makes a mistake?”

Depending on what kind of mistake, there are controlled ways to correct it — an adjustment for a stock-count correction, or a transfer or return for stock that’s simply in the wrong place. Nothing is silently overwritten; every correction is itself a recorded transaction.

The Master Script

This is the walkthrough itself. Read the plain paragraphs aloud, in order, and follow the ACTION lines as you go.

Opening

Good morning/afternoon, and thank you for the time today. What I want to show you isn't a list of features — it's how your stock actually moves through your organisation from the moment it arrives, to the moment it's used, and everything in between.

Cobro IMS is the system that keeps track of all of that in one place. It doesn't matter whether we're talking about an ordinary stock item or a repair part — the system manages it the same way, through the same process, with the same visibility. I'll show you exactly what that looks like, following one connected story from start to finish, rather than jumping between unrelated screens.

I'll be moving between a couple of different user accounts as we go, because in a real organisation, different people are responsible for different steps — and I want you to see that handover happen exactly as it would day to day.

PART 1 — SYSTEM OVERVIEW

[EXPLAIN] Before I show you anything on screen, I want to give you the shape of the whole system in one breath, so everything that follows makes sense as it happens.

At its core, Cobro IMS answers three questions at all times: what stock do we have, where is it, and what has happened to it. It covers stock sitting in your main store, stock that's been issued out to an Engineer, stock moving between locations, stock being requested, received, issued, returned or adjusted, and it gives management a full financial and operational view over all of it through reporting.

One thing I want to be clear about from the outset: repair items are not a separate system running alongside the normal one. A repair part is simply a product in the catalogue, marked with a "Repair items" category so it's always visible at a glance — but it's received, requested, moved, scanned and reported on through exactly the same process as everything else. I'll point that out again when we see it, but it's worth saying up front: one system, one process, for every type of stock you hold.

PART 2 — LOGIN / USER EXPERIENCE

[NAVIGATE] I'll start by logging in exactly as any user would, so you can see the very first thing someone experiences when they open the system.

ACTION: *Open the login page. Do not log in yet.*

[DEMONSTRATE] As you can see, it's a straightforward sign-in — an email address, a password, and an option to stay signed in on this device.

ACTION: *Type the Admin account's email and password, then submit.*

[EXPLAIN] One thing worth knowing: for any user who has an extra layer of verification enabled on their account, the system will ask for a short code from their authenticator app immediately after their password, right here on this same screen, before they're let in. I'll show you that layer of security properly a little later, at the point in the process where it's actually required.

[IMPORTANT / BACKUP] If this account does prompt for a code, enter it now before continuing. If it doesn't, that simply means this particular account doesn't have that extra layer switched on — which is a per-user setting, not a limitation of the system.

PART 3 — DASHBOARD

[NAVIGATE] Once you're signed in, this is the very first thing you see — the Overview.

[EXPLAIN] This page is designed to answer one question immediately: “what do I need to know right now?” At the top, you can see how many different products are being tracked, the current value of everything on hand, and how many items have fallen below the stock level you've told the system to warn you about. If that last number is ever above zero, it's shown in a way that draws your eye to it — you don't have to go looking for a problem, the system surfaces it to you.

[DEMONSTRATE] Further down, you can see stock broken down by location — what's physically in the store, and what's currently out with different people. I'll come back to this exact view a few times today, because it's where you'll actually watch the effect of everything else we do.

PRESENTER NOTE: What appears on this page changes depending on who's logged in. As Admin, you're seeing the full picture. When I switch to the Engineer's account later, you'll notice this same page looks a little different — because an Engineer's day-to-day priorities aren't the same as Admin's, so the system shows each of them what's relevant to their own role.

PART 4 — PRODUCT CATALOGUE

[NAVIGATE] I'll move now to the Product Catalogue, because before we can talk about receiving, requesting or moving stock, it helps to see what “a product” actually looks like inside the system.

[DEMONSTRATE] Every item your organisation stocks lives here, with a small set of information that keeps everything else in the system working correctly. Each product has a unique code — a SKU — which is what lets the system know exactly which item we're dealing with, whether it's being received, requested, scanned or reported on. Alongside that, you'll see the product's name, its unit of measure — how it's actually counted — its barcode, which is what allows physical scanning, its category, and a reorder point, which is the stock level that triggers a low-stock warning.

ACTION: Point to the “Steel Trowel” row, then the “Concrete Pump Motor” row.

[IMPORTANT / BACKUP] This is the moment to make the key point of the whole presentation. Point at the category column.

[EXPLAIN] Notice this item is tagged “Repair items”, and this one isn’t. That tag is the only difference between them as far as the system is concerned. Everything I’m about to show you — receiving, requesting, approving, transferring, scanning, reporting — works exactly the same for both. The category simply lets anyone looking at a screen instantly recognise which items are repair-related, without needing a second system to track them separately.

[DEMONSTRATE] You’ll also notice that category badge doesn’t just live here — it follows the product wherever it appears throughout the system: on receiving screens, requisitions, transfers, scan results, and every relevant report. Wherever you see this item today, you’ll see that same tag.

PART 5 — STOCK LOCATIONS

[NAVIGATE] I’ll go back to the Overview briefly, to show you how the system thinks about where stock actually is.

[EXPLAIN] The system doesn’t just tell us how much of an item exists — it also tells us where it currently sits. Broadly, stock lives in one of two kinds of place: your Stores — the physical warehouse — or an Engineer’s own personal station.

An Engineer Station is simply a personal holding location that belongs to one individual. When stock is issued to an Engineer, it doesn’t just disappear from the system’s view — it moves to their own station, and stays visible and tracked there until they use it or return it. You’ll see exactly how that happens shortly.

[DEMONSTRATE] On this stock-by-location view, you can switch between seeing stock by Station or by Store, and for every row you’ll see how much is on hand, and how much of that is already reserved against a request — I’ll explain reservation properly in a few minutes, once we’ve actually created one.

PART 6 — RECEIVING

[NAVIGATE] I’ll move now to how stock actually enters the organisation in the first place — Goods Receiving.

[EXPLAIN] This is where stock physically arrives. Rather than someone simply typing in a new stock number by hand, the person receiving the delivery scans or selects the product, confirms the store it’s going into, the quantity, and the cost, and the system records it as a proper receipt — not just a number change.

[DEMONSTRATE] I’ll receive some stock now.

ACTION: *On the Overview or the Goods receiving page, scan or type the barcode for “Steel Trowel”, confirm the store, enter a quantity, and submit.*

[EXPLAIN] That’s it — the moment I submitted that, the system posted a real stock movement. It didn’t just change a number on a screen; it created a permanent record that this exact quantity of this exact product arrived, in this store, at this time. I’ll show you that record again later, in the history.

PRESENTER NOTE: There is also a full, formal Purchase Order process available — draft an order, issue it to a supplier, and receive against it, potentially in more than one delivery. What I've just shown you is the quick option for a delivery that doesn't need a formal order raised first. Both paths lead to the same place: real stock, properly recorded, in Stores.

PART 7 — STOCK POSITION

[NAVIGATE] Now that we've received that stock, let's go and look at what's actually changed.

ACTION: *Navigate back to the Overview's stock-by-location table, or the Product catalogue.*

[DEMONSTRATE] You can see the on-hand quantity for this item has gone up by exactly what we just received. Nobody had to go and manually update a total anywhere — the receipt we just posted is what moved this number.

PART 8 — REQUISITION: RAISING A REQUEST

[ROLE SWITCH] The next step in the story starts with the person who actually needs the stock — not Stores, and not Admin. So I'm going to sign out and sign back in as an Engineer, to show you the process from their side.

ACTION: *Sign out of the Admin account. Sign in as the Engineer / Requester demo account.*

[EXPLAIN] This is the Engineer's view of the same system. Notice it looks a little different to what we saw as Admin — there's no product catalogue management here, no receiving. What this person sees is scoped to what's actually relevant to their job: their own stock, and the ability to request more.

[NAVIGATE] I'll move to Requisitions.

[DEMONSTRATE] This is where an Engineer asks for stock they need. They scan or select the product, choose which department or workshop the request is for, which store it's coming from, and how much they need.

ACTION: *Scan or select "Concrete Pump Motor", choose the requesting department and store, enter a quantity, and create the requisition.*

[EXPLAIN] At this point, nothing has actually happened to stock yet. This request exists as a draft — it reserves nothing and moves nothing until someone with the right authority reviews it. That's deliberate: an Engineer can ask for what they need, but they can't simply take it.

PART 9 — APPROVAL

[ROLE SWITCH] The request has now been submitted, and responsibility moves to whoever is authorised to review it. I'll switch back to the Admin account for this.

ACTION: *Sign out of the Engineer account. Sign in as Admin. Navigate to Requisitions.*

[DEMONSTRATE] Here's the request we just raised, sitting as a draft. I'll approve it now.

ACTION: Click Approve on the new requisition.

[EXPLAIN] The request has now been approved, which means the stock has been reserved for it. This is an important distinction: the stock hasn't physically gone anywhere yet — it's still sitting in the store — but it's now been set aside for this specific request, so nobody else can accidentally use it for something else.

[DEMONSTRATE] If we look at the stock-by-location view now, you'll see this item shows a reserved quantity alongside the on-hand quantity. It's still physically on the shelf and still counted in your total stock value — it's just no longer free to give to someone else.

PART 10 — STORES / DISPATCH

[EXPLAIN] Approval on its own doesn't move any physical stock — it only reserves it. The next step is what actually changes the physical position: dispatching, or issuing, the stock.

In this system, that final step can be done in one of two ways, depending on the situation. A Stores user can issue it directly. Or — and this is worth highlighting — the Engineer who originally asked for it can accept it themselves, once it's been approved. I'll show you that second path now, because it reflects how stock pickup actually happens day to day: the Engineer comes and collects what's been approved for them.

PART 11 — ENGINEER ACCEPTANCE

[ROLE SWITCH] I'll switch back to the Engineer's account, because this next step is theirs to complete.

ACTION: Sign out of Admin. Sign in as the Engineer / Requester account. Navigate to Requisitions.

[DEMONSTRATE] This request now shows as approved, with an option to accept it.

ACTION: Click Accept on the approved requisition.

[EXPLAIN] The moment I did that, the stock genuinely moved — it left the store and landed on this Engineer's own personal station. The request itself now shows as issued, meaning the full journey, from request to delivery, is complete and recorded.

[NAVIGATE] Let's go and confirm that on the stock-by-location view.

[DEMONSTRATE] Here it is — sitting on the Engineer's own station, ready for them to use.

PART 12 — TRANSFERS

[NAVIGATE] Stock doesn't always stay exactly where it was first received or issued. Sometimes it needs to move between locations directly — that's what Transfers are for. I'll show you that now.

[EXPLAIN] A transfer works in two stages, quite deliberately. The moment a transfer is started, the stock leaves the source location immediately — but it doesn't instantly appear at the destination. It sits in a state called "in transit" until the receiving side confirms it has arrived. That matters because it means stock is never counted as being in two places at once — and if a delivery goes missing between two points, you can see exactly where it stalled.

[DEMONSTRATE] I'll start a transfer now.

ACTION: *Navigate to Transfers. Choose a source and destination, select a product, enter a quantity, and initiate the transfer.*

[EXPLAIN] You can see it now sitting as "in transit". The stock has already left the source — it's no longer counted there — but it hasn't yet landed at the destination.

[DEMONSTRATE] Now I'll complete it from the receiving side.

ACTION: *Click "Scan to receive" (or "Mark received") on the transfer, and confirm.*

[EXPLAIN] And now it shows as completed, and the stock is properly reflected at its new location.

PART 13 — RETURN TO STORES

[EXPLAIN] Not everything issued to an Engineer necessarily gets used. Where stock isn't needed after all, the system allows it to be returned to Stores, rather than just sitting on someone's station indefinitely, quietly making the stock position inaccurate.

[NAVIGATE] I'll show you that now, still logged in as the Engineer.

ACTION: *On the Overview's stock-by-location table, find the item on the Engineer's station and click "Return to Stores".*

[DEMONSTRATE] Confirm the quantity being returned and submit.

[EXPLAIN] That stock is now on its way back to Stores — using exactly the same in-transit process I just showed you with transfers, because that's genuinely what a return is: a transfer back to the store, initiated by the person holding the stock. Once Stores confirms receipt, it's back in the store's own available stock.

PART 14 — SCANNER

[NAVIGATE] I'll move now to the barcode scanning screen, because everything I've shown you so far can also be driven directly from a physical barcode, rather than searching for a product on screen.

[EXPLAIN] This one screen covers four things: scanning something in as a receipt, scanning something out as an issue, simply looking an item up without changing any stock, and — for an Engineer — recording an item on their own station as used.

[DEMONSTRATE] I'll scan the repair item now, just to look it up.

ACTION: Select "Look up only" mode, scan or type the barcode for "Concrete Pump Motor".

[EXPLAIN] You can see it's recognised the product instantly, shows the same "Repair items" tag we saw in the catalogue, and shows exactly how much is currently on hand, broken down by location — without changing anything.

[DEMONSTRATE] Now I'll switch to Use mode and record some of it as consumed.

ACTION: Switch to "Use" mode, scan the same barcode.

[EXPLAIN] That has just reduced the stock on this Engineer's own station by exactly one unit, and recorded it permanently as stock that has now left the organisation's tracked inventory for good — because it's actually been used.

PART 15 — ADJUSTMENTS

[ROLE SWITCH] Adjustments are a more sensitive part of the system, so I'll switch to an Admin account for this — specifically, one that has the extra security step enabled, because you'll see why that matters in a moment.

ACTION: Sign out. Sign in as the Admin account prepared with 2FA enrolled. (Only Admin can approve an adjustment — a Stores Manager can raise one but not approve it — so this must be an Admin account.)

[IMPORTANT / BACKUP] If this account has 2FA enrolled, you'll be asked for the authenticator code right here, immediately after signing in — before you even reach the dashboard. Enter it now. By the time we reach the Approve step below, this session will already be fully verified, so clicking Approve will go straight through without asking again.

[NAVIGATE] I'll move to Write-offs & Adjustments.

[EXPLAIN] Not every stock discrepancy is a request, a receipt or a transfer. Sometimes stock simply needs to be corrected — damage, a stock count that doesn't match, or a similar reason. That's what this section is for.

[DEMONSTRATE] Raising an adjustment is straightforward — but notice that raising one, on its own, doesn't change any stock yet either. It goes into a pending state, exactly like a requisition does, until someone with the authority to approve it reviews it.

ACTION: Create an adjustment against the demo product, selecting a reason and quantity.

[IMPORTANT / BACKUP] Approving this is one of the most sensitive actions in the entire system, because it directly changes your stock position with no second person double-checking it afterwards. That's why the system requires an extra step here.

[DEMONSTRATE] I'll approve it now.

ACTION: Open the pending adjustment and click Approve.

[EXPLAIN] Notice that went through immediately, with no extra prompt on this screen — because this account already proved its identity with a verification code from an authenticator app the moment we signed in, before we could even reach the dashboard. That verification isn't required just to log in and raise a request; it's specifically required for an account that's allowed to approve — the single most sensitive action in the system, where stock actually changes with no second person double-checking it afterwards. Only an already-verified, 2FA-enrolled session was allowed to complete that approval.

PART 16 — MOVEMENT / AUDIT HISTORY

[NAVIGATE] I'll move now to the history section, so we can look back at everything we've actually just done.

[EXPLAIN] One of the most important things about an inventory system isn't just knowing where stock is right now — it's knowing what happened to it, and who was responsible.

[DEMONSTRATE] Here you can see a running record of every action — who performed it, what it was, and exactly when it happened. This record can't be edited or deleted afterwards, which means it's a genuine, permanent history, not just a status that could quietly be changed later.

If we scroll through, you can actually see the receipt, the requisition approval, the acceptance, the transfer and the adjustment we've just walked through, each one attributed to the account that performed it.

PART 17 — REPORTS

[NAVIGATE] Now that we've built up some real activity, I'll move into Reports, to show you how all of that comes together for management.

[EXPLAIN] There's a full set of standard reports here, and each one is built to answer a specific business question — not just to show raw data.

Stock valuation — how much inventory are we currently holding, and what is it worth?

Low stock / reorder suggestions — which items need attention because they've dropped below their reorder point?

Dormant stock — which items haven't moved and may need review?

Requisition summary — what has each department requested, and where does it stand?

Pick list — what's approved and ready to be physically picked?

Purchase order summary and Open purchase orders — what have we ordered, and what's still outstanding?

Stock movement history and Receiving history — the full transaction trail behind every number.

Adjustment reason summary — how many corrections have been raised, and why.

There are a few more besides — including store-level, department-level and supplier-level summaries, and a roll-up of movement types — available if the client wants to go deeper in a follow-up session.

[DEMONSTRATE] Every one of these can be exported, so this information isn't locked inside the system.

ACTION: Point to the export/CSV option on any report.

PART 18 — STOCK VALUATION

[NAVIGATE] I want to spend a moment specifically on Stock Valuation, because it directly reflects everything we've done today.

[EXPLAIN] We received stock into the store earlier. Some of that stock was then requested, approved and issued. This report shows you what all of that leaves you holding, and what it's worth, based on the average cost of each item — giving management a real financial view of inventory, not just a unit count.

[DEMONSTRATE] Point to the value for the demo product and connect it back to the earlier receipt.

PART 19 — LOW STOCK / DORMANT STOCK

[NAVIGATE] Two more reports worth highlighting for day-to-day management.

[EXPLAIN] Low stock tells you immediately which items have fallen below the level you've decided is acceptable, so replenishment can be planned before it becomes a problem. Dormant stock does the opposite job — it flags items that simply haven't moved, which is often just as useful to know, because it can point to stock that's no longer needed or has been forgotten.

PART 20 — ADMINISTRATION / OVERSIGHT

[NAVIGATE] Finally, I'll show you, briefly, how the organisation maintains control over who can do what.

[EXPLAIN] Admin manages every user account, assigns each person their role, and can see exactly what each role is able to do. Different roles genuinely see different things and can perform different actions — you'll have noticed throughout this walkthrough that the Engineer's account couldn't do what the Admin account could, and that's intentional. Responsibility is matched to role, on purpose, throughout the whole system.

[DEMONSTRATE] Briefly show the Users page, without changing anything on a real account.

Closing

To bring everything together: what you've seen today is that Cobro IMS isn't simply a list of stock. It follows the actual journey of that stock through your organisation — from the moment it arrives in Stores, through requests, approvals and dispatches, out to the people who need it, and back again if it isn't used — and every one of those steps is recorded automatically, permanently, and attributed to the person responsible for it.

Whether we're talking about an ordinary item or a repair part makes no difference to how the system treats it — one process, one record, one source of truth for everything you hold. And at every point along the way, management has real visibility: what you have, what it's worth, what's running low, and exactly what's happened to get you there.

I'm happy to answer any questions, or go back into any part of this in more depth.
