

COBRO IMS

Client System Walkthrough

Presenter's Script & Demonstration Guide — v2

This is a spoken script. Every navigation, click, selection, entry, scan, filter, submission, approval and role switch is written INTO the sentence you say — there is nothing left for you to do silently. Read the plain paragraphs aloud, in your own voice, and perform the action they describe as you say them.

This version also deliberately works in everything the client has raised in previous meetings — the For Use / For Repair distinction, repair costing, the additional roles, Engineer reminders, and the monthly stock accountability idea. Where the system genuinely does this today, it is demonstrated. Where it doesn't yet, that is said honestly, as a confirmation point with the client, not glossed over and not faked.

For internal presenter use only — not for distribution to the client.

How to Use This Document

Every plain paragraph below is something you say to the client, in your own natural voice, while you perform the action it describes. There are no separate “ACTION:” instructions anywhere in this document — the sentence itself tells you what to click, select, type or do, and why.

Lines starting with “PRESENTER NOTE:” are background for you only — do not read these aloud.

The markers used throughout:

Marker	Meaning
[NAVIGATE]	A spoken paragraph that both explains why, and tells you which screen you are moving to as you say it.
[DEMONSTRATE]	A spoken paragraph that both explains why, and tells you what you are clicking, selecting, typing or submitting as you say it.
[EXPLAIN]	A spoken paragraph with no action — just talk the audience through a concept.
[ROLE SWITCH]	A spoken paragraph that both explains why responsibility is moving to a different person, and tells you to sign out and sign back in as you say it.
[IMPORTANT / BACKUP]	A caution to keep in mind, or a ready-made fallback sentence if something on screen doesn't behave exactly as expected.
[CLIENT CONFIRMATION]	A moment to pause and ask the client a specific question, worded so it sounds like a professional next step, not a gap in the system.

PRESENTER NOTE: Everywhere this script names a specific product, it uses the placeholder “Concrete Pump Motor” for a repair item and “Steel Trowel” for an ordinary stock item, and it uses “No. 2 Machine” as an illustrative example of the asset that item was needed for. These are example names only, and “No. 2 Machine” is spoken, not captured anywhere in the system yet — see the Client Confirmation points in Part 8 for why. Substitute your own product names as needed.

Pre-Demo Checklist

Everything below should be confirmed or completed before you sit down with the client. None of it needs to be done live.

1. Rename the demo products — highest priority

The two products set up for testing are named “Regression Test Normal” and “Regression Test Repair”. *(Confirm these are still the actual names in your live system before tomorrow.)* Rename them to something presentable — for example “Steel Trowel” and “Concrete Pump Motor” (kept in the existing “Repair items” category). This does not affect the barcode, stock levels, or any history already built up against them.

2. Confirm your demo accounts

An Admin account, ready to use, for the Product Catalogue, approving requisitions, Receiving, Reports, Audit Log and Users sections.

A second **Admin** account with 2FA already enrolled and working, kept specifically for the Adjustments **approval** step. This must be Admin, not Stores Manager — only Admin can approve an adjustment in the current permission model.

An Engineer / Requester account, ready to use — the account that owns a personal station, and lets you show Scan-to-Use, self-accepting a requisition, and Return to Stores.

If you intend to show Stores Clerk, Supervisor, Mechanical Team Leader or Electrical Team Leader as well, confirm a working login exists for each and none is stuck on a temporary first-login password.

3. Confirm the demo product's stock position

Both demo products have a barcode assigned, and a real, non-zero quantity on hand in the main store, so the requisition has genuine stock to reserve.

The reorder point is set at a level that suits what you want to show.

4. Leave the existing transaction history in place

There is already a short, genuine history against the repair-item product from earlier testing — build on top of it rather than starting from zero.

5. Decide how you will speak about the repair example

Because the system does not yet capture a repair description or an asset/site reference as a field (see the Client Confirmation points in Part 8), the “No. 2 Machine” example in this script is something you SAY to the client, not something you type into the system. Decide beforehand whether you want to use that example, or a real example from Cobro's own operation, so it lands naturally rather than sounding rehearsed.

6. Purchase Orders (only if you plan to show this module)

Have at least one supplier set up, and ideally one Purchase Order already issued with an outstanding quantity.

7. Have your own authenticator app ready

For your day-to-day account and for the dedicated 2FA Admin account, open the authenticator app on your phone before you start.

8. Close other sessions

Make sure no other browser tab or window is signed in as a different Cobro user.

Live Demo Safety Guide

Every action below is real — nothing in Cobro IMS is a simulated demo mode.

Action	What actually happens	Recommendation
Receiving stock (quick receive)	Permanently increases stock on hand.	Safe to do live, freely.
Creating a requisition (draft)	No stock effect until approved.	Safe to do live, freely.
Approving a requisition	Reserves real stock against that request.	Safe to do live, freely.
Dispatching / issuing a requisition	Posts a real stock movement, moves stock to the requester's station.	Safe live — do it once per rehearsed sequence.
Engineer accepting their own requisition	Same effect as above.	Safe live.
Scan-to-Use	Permanently reduces stock; cannot be undone except by a separate adjustment.	Rehearse once beforehand.
Initiating a transfer	Immediately removes stock from the source into an in-transit state.	Safe live — complete the receiving side in the same segment.
Return to Stores	Removes stock from the Engineer's station into transit back to the store.	Safe live.
Requesting an adjustment	No stock effect until approved.	Safe live.
Approving/rejecting an adjustment	Permanently changes stock; requires a verified 2FA session.	Rehearse beforehand with the 2FA-ready Admin account.
Changing a user's role or permissions	Affects a real account immediately.	Avoid live unless specifically asked.
Deactivating a user	Immediately blocks that account from logging in.	Avoid live unless specifically asked.

Backup Plans

If any live step doesn't behave as expected, you don't need to explain anything — pivot naturally to something already on record.

Login is slow

[IMPORTANT / BACKUP] “While that comes up, let's talk through what a user sees the moment they open the system.” Keep describing the visible login fields while it loads.

Receiving doesn't go as planned

[IMPORTANT / BACKUP] “Rather than create a brand new receipt, let's look at one we already have on record.” Navigate to Dashboards & reports → Receiving history and point to an existing line.

A new requisition doesn't behave as expected

[IMPORTANT / BACKUP] “I can see this one is already sitting at exactly the stage we want, so let's continue from here instead.” Use an existing requisition rather than the one just created.

Dispatch / acceptance doesn't complete cleanly

[IMPORTANT / BACKUP] “This request has already been through exactly this step — let's look at what it looks like once it's been accepted.” Point to an existing requisition already showing “Issued”.

A transfer doesn't complete

[IMPORTANT / BACKUP] “Let's look at a transfer that's already been completed.” Navigate to Transfers and point to an existing row marked “Completed”.

The camera scanner won't cooperate

[IMPORTANT / BACKUP] “The same result works by simply typing the barcode number in — the system treats it identically.” Type the digits by hand instead.

The 2FA approval step stalls

[IMPORTANT / BACKUP] “Let me show you an adjustment that's already been through this exact process.” Navigate to Dashboards & reports → Adjustment reason summary, or the Audit log.

A report looks emptier than expected

[IMPORTANT / BACKUP] “Let's widen this slightly.” Clear or broaden any product/date filter — reports are read-only, so there is no risk in experimenting live.

Role Relationship Overview

Cobro IMS has seven configured roles today. They represent different responsibilities in the same, single stock process — the script moves between roles exactly where responsibility genuinely changes hands.

Role	Status	Their role in the process
Admin	Configured	Full oversight: product catalogue, users, suppliers, pricing, and the organisation's most sensitive actions such as approving a stock adjustment. Does not raise requisitions — Admin's equivalent is a Purchase Order to a supplier.
Stores Manager	Configured	Purchase orders, receiving, transfers, and can raise (though not approve) a stock adjustment.
Stores Clerk	Configured	Day-to-day store operations — purchase orders, receiving and transfers, like Stores Manager, but without the ability to raise an adjustment.
Stores Assistant	Not yet configured	Raised in a previous meeting as a wanted role. Today, Stores Clerk is the closest existing equivalent. Whether Stores Assistant needs to be its own role with different permissions, or whether Stores Clerk already covers it under a different name, is a confirmation point — see Part 20.
Engineer / Requester	Configured	Raises a request for stock, works from their own personal holding location, can accept their own approved request, record stock as used, and return anything not needed.
Supervisor	Configured	Oversight across requisitions and reporting, without store-management responsibility.
Mechanical Team Leader	Configured	The same requisition and reporting oversight as a Supervisor, scoped to the Mechanical team.
Electrical Team Leader	Configured	The same requisition and reporting oversight as a Supervisor, scoped to the Electrical team.

How responsibility actually moves through the system:

1. An Engineer / Requester raises a requisition for what they need.
2. An authorised Stores user (or Admin) reviews it and approves it — this reserves the stock.
3. The requisition is then dispatched — either by Stores, or by the Engineer accepting their own approved request.
4. The stock arrives at the Engineer's own personal station.
5. The Engineer records it as used, or returns it to Stores if it isn't needed.
6. Every one of these steps is recorded automatically.
7. Reports and the Dashboard give Admin, Supervisors and Team Leaders visibility across all of it.

PRESENTER NOTE: The 7 roles above, their two reporting chains, and the rule that Admin never raises a requisition, are all confirmed. A handful of finer details — a distinct Stores Assistant role, and exactly what a Team Leader can do beyond viewing — are open points, addressed explicitly in Part 20 rather than glossed over.

Anticipated Client Questions

Short, accurate, natural answers — grounded in what the system actually does today.

“What happens if we don’t have enough stock?”

The system won’t let a request move forward if there isn’t enough available stock to reserve. If someone tries to approve more than what’s actually available, it stops them and explains why, rather than letting the stock position go negative.

“Who approves a request?”

That depends on where the stock is coming from. If it’s coming from the main store, an authorised Stores user or Admin reviews and approves it. If it’s a request between two Engineers’ own stock, the Engineer who owns that stock approves it themselves.

“Can an Engineer request stock?”

Yes — that’s exactly how the process starts. An Engineer raises the request, and once it’s approved and issued, the stock lands on their own personal station.

“Where does the Engineer’s stock go?”

Every Engineer has their own personal holding location in the system — their station. Stock sits there, visible and tracked, until they use it or return it.

“Can stock be returned?”

Yes, from an Engineer’s station back to Stores, recorded as its own transaction.

“Can we see where stock is?”

Yes — current stock by location, always: what’s in the store, and what’s currently held by each Engineer.

“How do we know who changed something?”

Every stock-affecting action is recorded with who did it and when, in a history that cannot be edited or deleted afterwards.

“Can everyone perform adjustments?”

No. Only specific roles can raise one, and approving it — the step that actually changes stock — needs a verified second-factor code, because it’s one of the most sensitive actions in the system.

“What happens when stock is transferred?”

It leaves the source location immediately and is shown as in transit — not yet added at the destination — until the receiving side confirms it has arrived. Stock is never counted as existing in two places at once.

“How do we know how much our stock is worth?”

There’s a dedicated valuation report showing the value of everything currently held, based on the average cost of each item.

“How do we identify low stock?”

There’s a report for that — anything that has dropped below the reorder point you’ve set for it.

“Can we scan items?”

Yes — barcodes look an item up, receive it in, issue it out, or record it as used, from one scanning screen.

“Can we see the total material cost of a specific repair?”

Not as one combined figure today — that's one of the points we've captured from previous discussions, and I want to walk you through exactly what that would need and confirm the detail with you when we reach Reports.

“What happens when someone makes a mistake?”

Depending on the kind of mistake, there are controlled ways to correct it — an adjustment for a stock-count correction, or a transfer/return for stock in the wrong place. Nothing is silently overwritten; every correction is itself a recorded transaction.

The Master Script

Read every plain paragraph aloud, in order. Each marked paragraph both tells the client something and tells you what to do — there is nothing else to remember alongside it.

Opening

Good morning/afternoon, and thank you for the time today. What I want to show you isn't a list of features — it's how your stock actually moves through your organisation, from the moment it arrives, to the moment it's used, and everything in between.

Cobro IMS is the system that keeps track of all of that in one place. It doesn't matter whether we're talking about an ordinary stock item or a repair part — the system manages it the same way. I'll show you exactly what that looks like, following one connected story from start to finish, rather than jumping between unrelated screens. Along the way, I also want to walk you through a few specific points you've raised with us before — how a repair should be identified, and how its cost should be tracked — and be straightforward with you about exactly what's built today and what we still need to confirm together.

I'll be moving between a couple of different user accounts as we go, because in a real organisation, different people are responsible for different steps — and I want you to see that handover happen exactly as it would day to day.

PART 1 — SYSTEM OVERVIEW

[EXPLAIN] Before I show you anything on screen, I want to give you the shape of the whole system in one breath, so everything that follows makes sense as it happens.

At its core, Cobro IMS answers three questions at all times: what stock do we have, where is it, and what has happened to it. It covers stock in your main store, stock issued out to an Engineer, stock moving between locations, and stock being requested, received, issued, returned or adjusted — and it gives management a full financial and operational view over all of it through reporting.

One thing I want to be clear about from the outset: repair items are not a separate system running alongside the normal one. A repair part is simply a product in the catalogue, marked with a "Repair items" category so it's always visible at a glance — but it's received, requested, moved, scanned and reported on through exactly the same process as everything else. What I want to build on top of that today is your specific requirement: not just knowing THAT a repair item was used, but knowing WHICH repair it was used for, and what that repair cost in materials. I'll show you exactly how far that already goes, and where we still need to finish the conversation.

PART 2 — LOGIN / USER EXPERIENCE

[NAVIGATE] I'll open the login page now, without signing in yet, so you can see the very first thing anyone experiences when they open the system.

[DEMONSTRATE] As you can see, it's a straightforward sign-in — an email address, a password, and an option to stay signed in on this device. I'm going to type the Admin account's email and password now and submit it.

[EXPLAIN] One thing worth knowing before I do: for any user who has an extra layer of verification switched on for their account, the system will ask for a short code from their authenticator app immediately after their password, right here on this same screen, before they're let in. I'll show you that layer of security properly a little later, at the point in the process where it's actually required.

[IMPORTANT / BACKUP] If this account does prompt for a code, enter it now before continuing. If it doesn't, that simply means this particular account doesn't have that extra layer switched on — a per-user setting, not a limitation of the system.

PART 3 — DASHBOARD

[NAVIGATE] Once I'm signed in, this is the very first thing I see — the Overview, so let's stay here for a moment.

[EXPLAIN] This page is designed to answer one question immediately: “what do I need to know right now?” At the top, I can see how many different products are being tracked, the current value of everything on hand, and how many items have fallen below the stock level we've told the system to warn us about. If that last number is ever above zero, it's shown in a way that draws the eye to it — nobody has to go looking for a problem, the system surfaces it.

[DEMONSTRATE] Further down, I can show you stock broken down by location — what's physically in the store, and what's currently out with different people. I'll come back to this exact view a few times today, because it's where we'll actually watch the effect of everything else we do.

PRESENTER NOTE: What appears on this page changes depending on who's logged in. As Admin, you're seeing the full picture. When we switch to the Engineer's account later, this same page genuinely looks different for them — not just cosmetically, but which stock it opens on. I'll point that out properly when we get there, as part of addressing what an Engineer's own dashboard should show them.

PART 4 — PRODUCT CATALOGUE

[NAVIGATE] I'll move now to the Product Catalogue, because before we talk about receiving, requesting or moving stock, it helps to see what “a product” actually looks like inside the system.

[DEMONSTRATE] Every item your organisation stocks lives here. Each product has a unique code — a SKU — which is what lets the system know exactly which item we're dealing with wherever it's received, requested, scanned or reported on. Alongside that you'll see the product's name, its unit of measure, its barcode for physical scanning, its category, a reorder point, and — importantly for what we're about to discuss — a cost value that lives on the product record itself, not with whoever happens to be requesting it. I'll point to the Steel Trowel row, and then the Concrete Pump Motor row, so you can see both side by side.

[IMPORTANT / BACKUP] This is the moment to make the key point of the whole presentation. Point at the category column as you say the next paragraph.

[EXPLAIN] Notice this item is tagged “Repair items”, and this one isn’t. That tag is the only difference between them as far as the system is concerned today — receiving, requesting, approving, transferring, scanning and reporting all work exactly the same for both. What that tag gives you is instant visual recognition of which items are repair-related. What it does not yet give you is a link to a SPECIFIC repair job — that’s a distinction I want to draw out carefully when we get to Requisitions, because it’s exactly the gap you’ve raised with us before.

[DEMONSTRATE] You’ll also notice that category badge doesn’t just live here — it follows the product wherever it appears: on receiving screens, requisitions, transfers, scan results, and every relevant report. Wherever we see this item today, we’ll see that same tag.

[EXPLAIN] I also want to point out the cost sitting on this product record, because it matters for a question you’ve raised: who decides what a material costs. That value is maintained here, centrally, and only an Admin can change it. That’s the correct principle — the person requesting stock shouldn’t be the one deciding what it’s worth. I’ll come back to exactly how far that principle currently reaches when we get to Requisitions, because there’s a specific point there I want to be completely straightforward with you about.

PART 5 — STOCK LOCATIONS

[NAVIGATE] I’ll go back to the Overview briefly, to show you how the system thinks about where stock actually is.

[EXPLAIN] The system doesn’t just tell us how much of an item exists — it also tells us where it currently sits. Broadly, stock lives in one of two kinds of place: your Stores — the physical warehouse — or an Engineer’s own personal station.

An Engineer Station is simply a personal holding location that belongs to one individual. When stock is issued to an Engineer, it doesn’t just disappear from the system’s view — it moves to their own station, and stays visible and tracked there until they use it or return it. You’ll see exactly how that happens shortly.

[DEMONSTRATE] I’ll switch this view between Station and Store now, so you can see both — and for every row you’ll notice how much is on hand, and how much of that is already reserved against a request. I’ll explain reservation properly in a few minutes, once we’ve actually created one.

[CLIENT CONFIRMATION] Before we go further, I want to confirm the naming with you directly, because it’s exactly this screen the client will look at day to day. The locations we’ve been calling “Stores” can be named however you want them seen throughout the system — the same applies to any Facility or Workshop location you want set up as its own place. Rather than me guessing at the right names, can we confirm the final names for each Store, Facility and Workshop you want your users to see, so we can set them up exactly that way before go-live?

PART 6 — RECEIVING

[NAVIGATE] I’ll move now to how stock actually enters the organisation in the first place — Goods Receiving.

[EXPLAIN] This is where stock physically arrives. Rather than someone simply typing in a new stock number by hand, the person receiving the delivery scans or selects the product, confirms the store it's going into, the quantity, and the cost, and the system records it as a proper receipt — not just a number change.

[DEMONSTRATE] I'll receive some stock now: I'm going to scan or type the barcode for the Steel Trowel, confirm the store it's going into, enter a quantity, and submit it.

[EXPLAIN] That's it — the moment I submitted that, the system posted a real stock movement. It didn't just change a number on a screen; it created a permanent record that this exact quantity of this exact product arrived, in this store, at this time. I'll show you that record again later, in the history.

PRESENTER NOTE: There is also a full, formal Purchase Order process — draft an order, issue it to a supplier, and receive against it, potentially in more than one delivery. What I've just shown is the quick option for a delivery that doesn't need a formal order raised first. Both paths lead to the same place: real stock, properly recorded, in Stores.

PART 7 — STOCK POSITION

[NAVIGATE] Now that we've received that stock, let's go and look at what's actually changed — I'll go back to the Overview's stock-by-location table.

[DEMONSTRATE] You can see the on-hand quantity for this item has gone up by exactly what we just received. Nobody had to go and manually update a total anywhere — the receipt we just posted is what moved this number.

PART 8 — REQUISITION: RAISING A REQUEST, AND THE REPAIR STORY

[ROLE SWITCH] The next step in the story starts with the person who actually needs the stock — not Stores, and not Admin. So I'm going to sign out of the Admin account now and sign back in as the Engineer, to show you the process from their side.

[EXPLAIN] This is the Engineer's view of the same system. Notice it looks a little different to what we saw as Admin — there's no product catalogue management here, no receiving. What this person sees is scoped to what's actually relevant to their job: their own stock, and the ability to request more. I'll come back to exactly what's different about this Engineer view in a moment — it's one of the things you've specifically asked us about.

[NAVIGATE] I'll move to Requisitions now, because this is where an Engineer asks for stock they need.

[DEMONSTRATE] I'm going to create a new requisition here for the Concrete Pump Motor. The form is asking me for the department the request is for, the store it's coming from, and how much I need — I'll fill those in and select the product from the catalogue rather than typing anything by hand, because that way we're always working against the same product record and its information, not a description someone's typed slightly differently this time.

[EXPLAIN] At this point, nothing has actually happened to stock yet. This request exists as a draft — it reserves nothing and moves nothing until someone with the right authority reviews it. That's deliberate: an Engineer can ask for what they need, but they can't simply take it. I'm not going to submit it yet, though, because I want to stop here and talk you through exactly what this request does and doesn't capture today, since this is the heart of what you've raised with us.

[IMPORTANT / BACKUP] This next section is the most important part of the whole walkthrough for you. Slow down here.

[EXPLAIN] You've told us before that when someone requests stock, the system should ask a simple question up front: is this material for general use, or is it for a specific repair? If it's a repair, you want the person raising the request to record what the repair actually is, and which piece of equipment it relates to — for example, if this Concrete Pump Motor were going toward work on No. 2 Machine, you want that captured right here, at the point of the request, not worked out afterwards from someone's memory.

[CLIENT CONFIRMATION] I want to be completely straightforward with you: that For Use / For Repair choice, the repair description, and the link to a specific asset like No. 2 Machine, are not yet fields on this request form. What you see in front of you today is Department, Store, Product and Quantity. This is one of the requirements we've captured from our previous discussions, and I want to confirm the exact business rule with you now, while we're looking at the actual screen it would sit on: for "For Use," what exactly should that mean operationally — and for "For Repair," what information do you need captured at this point: a free-text description, a specific asset from a list, or both?

[CLIENT CONFIRMATION] And connected to that: what should the actual repair reference be that everyone works against — the asset itself, such as No. 2 Machine, a breakdown number, a job number, a repair number, or another reference you already use operationally today? Once we agree on that, it becomes the one identifier that carries the whole story through the system — the request, the approval, the issue, and eventually the cost report I'll show you later.

[EXPLAIN] What I can show you honestly, right now, is the cost side. When I select the Concrete Pump Motor as the product on this request, the Unit value field currently still needs to be typed in by whoever is raising the request — it does not yet pull automatically from the cost we saw a moment ago on the product record in the catalogue.

[CLIENT CONFIRMATION] That connects directly to your requirement that material cost should come from the Product Catalogue automatically, not be entered by hand at the point of request. We've captured that, and I want to confirm with you that the intent is exactly what it sounds like: the moment a product is selected here, its value should be pulled in from the catalogue record we looked at earlier, with no manual entry and no room for it to be typed incorrectly.

[DEMONSTRATE] With that context given honestly, I'll go ahead and submit the request as the form stands today, with the quantity and value filled in, so we can continue following it through the rest of the process.

PART 9 — APPROVAL

[ROLE SWITCH] The request has now been submitted, and responsibility moves to whoever is authorised to review it. I'll sign out of the Engineer account and back in as Admin for this.

[NAVIGATE] I'll navigate to Requisitions, where we can see the request we just raised, sitting as a draft.

[EXPLAIN] Before I approve it, I want to show you exactly what Stores sees on this row, because it connects directly to what we just discussed. Today, this line shows who requested it, which department, which product, the store, the quantity and the value, and its status. What it does not show is WHY the material is needed — whether it's general use or a specific repair.

[CLIENT CONFIRMATION] That's the second half of the same requirement we just discussed: Stores shouldn't just see "two units of a product" — they need to see the purpose. Once the For Use / For Repair field and the repair reference exist on the request, the natural next step is showing that same information here, on this list, so Stores can see it at a glance rather than having to ask. I want to confirm that's exactly what you have in mind before we treat this view as final.

[DEMONSTRATE] I'll approve it now.

[EXPLAIN] The request has now been approved, which means the stock has been reserved for it. This is an important distinction: the stock hasn't physically gone anywhere yet — it's still sitting in the store — but it's now been set aside for this specific request, so nobody else can accidentally use it for something else.

[CLIENT CONFIRMATION] While we're on approval, there's a related question worth settling now: today, every store-sourced requisition goes through the same Stores/Admin approval step, regardless of whether it turns out to be for general use or for a repair. Do you want that to stay a single approval path for both, or should a repair-related request be routed or flagged differently once we have that distinction in place?

[NAVIGATE] I'll move to the stock-by-location view now, so we can see that reservation reflected.

[DEMONSTRATE] Here you can see this item shows a reserved quantity alongside the on-hand quantity. It's still physically on the shelf and still counted in your total stock value — it's just no longer free to give to someone else.

[EXPLAIN] This distinction matters for Stores. On-hand tells us what physically exists here, while reserved tells us what has already been committed to an approved request.

PART 10 — STORES / DISPATCH

[EXPLAIN] Approval on its own doesn't move any physical stock — it only reserves it. The next step is what actually changes the physical position: dispatching, or issuing, the stock.

In this system, that final step can be done in one of two ways, depending on the situation. A Stores user can issue it directly. Or — and this is worth highlighting — the Engineer who originally asked for it can accept it

themselves, once it's been approved. I'll show you that second path now, because it reflects how stock pickup actually happens day to day: the Engineer comes and collects what's been approved for them.

PART 11 — ENGINEER ACCEPTANCE

[ROLE SWITCH] I'll sign out of Admin and sign back in as the Engineer, because this next step is theirs to complete.

[NAVIGATE] I'll navigate to Requisitions, where this request now shows as approved, with an option to accept it.

[DEMONSTRATE] I'm going to click Accept on the approved requisition now.

[EXPLAIN] The moment I did that, the stock genuinely moved — it left the store and landed on this Engineer's own personal station. The request itself now shows as issued, meaning the full journey, from request to delivery, is complete and recorded.

[CLIENT CONFIRMATION] This is the point where I want to check back in on the repair reference we talked about earlier. The whole reason that reference matters is traceability — we need it to still be sitting against this transaction now that it's been approved and issued, not just at the moment it was first requested. Once we've agreed the reference itself, I want to confirm with you that it should follow the transaction through every one of these steps, exactly the way the department and product already do.

[NAVIGATE] Let's go and confirm the physical result on the stock-by-location view.

[DEMONSTRATE] Here it is — sitting on the Engineer's own station, ready for them to use.

PART 12 — TRANSFERS

[NAVIGATE] Stock doesn't always stay exactly where it was first received or issued. Sometimes it needs to move between locations directly — I'll move to Transfers now to show you that.

[EXPLAIN] A transfer works in two stages, quite deliberately. The moment a transfer is started, the stock leaves the source location immediately — but it doesn't instantly appear at the destination. It sits in a state called "in transit" until the receiving side confirms it has arrived. That matters because it means stock is never counted as being in two places at once.

[DEMONSTRATE] I'll start a transfer now: choosing a source and destination, selecting a product, entering a quantity, and initiating it.

[EXPLAIN] You can see it now sitting as "in transit". The stock has already left the source — it's no longer counted there — but it hasn't yet landed at the destination.

[DEMONSTRATE] I'll now complete it from the receiving side, by clicking "Scan to receive" — or "Mark received" if scanning isn't required at this store — and confirming.

[EXPLAIN] And now it shows as completed, and the stock is properly reflected at its new location.

PART 13 — RETURN TO STORES, AND ENGINEER ACCOUNTABILITY

[EXPLAIN] Not everything issued to an Engineer necessarily gets used. Where stock isn't needed after all, the system allows it to be returned to Stores, rather than just sitting on someone's station indefinitely, quietly making the stock position inaccurate.

[NAVIGATE] I'll stay logged in as the Engineer and go to the Overview's stock-by-location table, finding the item on the Engineer's station.

[DEMONSTRATE] I'm going to click "Return to Stores" on it, confirm the quantity being returned, and submit.

[EXPLAIN] That stock is now on its way back to Stores — using exactly the same in-transit process I just showed you with transfers, because that's genuinely what a return is: a transfer back to the store, initiated by the person holding the stock. Once Stores confirms receipt, it's back in the store's own available stock.

[IMPORTANT / BACKUP] This next part directly answers something you've raised with us: making sure Engineers are reminded to use or return stock, not just issued it and forgotten.

[DEMONSTRATE] I'll click on the notification bell here, in the Engineer's own view.

[EXPLAIN] This is real, working today: if stock has been sitting on an Engineer's own station, untouched, for more than two weeks, it shows up right here as a reminder — telling that Engineer exactly which items, and prompting them to either use it or ask Stores to arrange a return. The same count rolls up for Stores and for Admin too, so nobody needs to go and check every Engineer's station individually to know what's sitting idle.

[CLIENT CONFIRMATION] What this doesn't yet do is follow a fixed monthly cycle — it's a standing reminder based on how long stock has been held, not a scheduled monthly process that formally offers each Engineer's outstanding stock back for confirmation. That monthly stock accountability idea is one we've captured from our previous discussions, and before we build the exact process, I'd like to confirm with you: who should initiate that monthly review, who approves the outcome, and what should actually happen for each item — confirmed as still needed, recorded as used, or returned?

PART 14 — SCANNER

[NAVIGATE] I'll move now to the barcode scanning screen, because everything I've shown you so far can also be driven directly from a physical barcode, rather than searching for a product on screen.

[EXPLAIN] This one screen covers four things: scanning something in as a receipt, scanning something out as an issue, simply looking an item up without changing any stock, and — for an Engineer — recording an item on their own station as used.

[DEMONSTRATE] I'll select "Look up only" mode first, and scan or type the barcode for the Concrete Pump Motor, just to look it up.

[EXPLAIN] You can see it's recognised the product instantly, shows the same "Repair items" tag we saw in the catalogue, and shows exactly how much is currently on hand, broken down by location — without changing anything.

[DEMONSTRATE] Now I'll switch to "Use" mode and scan the same barcode to record some of it as consumed.

[EXPLAIN] That has just reduced the stock on this Engineer's own station by exactly one unit, and recorded it permanently as stock that has now left the organisation's tracked inventory for good, because it's actually been used. This is exactly the moment your repair-costing requirement depends on most.

[CLIENT CONFIRMATION] We requested this Concrete Pump Motor against a specific repair earlier in the story. This scan is where that material is actually consumed — and this is where the connection between the material and the repair needs to be retained, so that later, when we ask what materials were used for this repair, the system can answer that directly rather than someone having to reconstruct it from memory. Today, this scan records that the item was used, but not which repair it was used for, for the same reason we discussed at the requisition step — that reference doesn't exist yet as a field to carry through to this point. I want to confirm this is understood as one continuous requirement, not two separate ones: the reference has to survive all the way from the original request through to this consumption step.

PART 15 — ADJUSTMENTS

[ROLE SWITCH] Adjustments are a more sensitive part of the system, so I'll sign out and sign back in as an Admin account for this — specifically, one that has the extra security step enabled, because you'll see why that matters in a moment. Only Admin can approve an adjustment — a Stores Manager can raise one but not approve it — so this has to be an Admin account.

[IMPORTANT / BACKUP] If this account has 2FA enrolled, you'll be asked for the authenticator code right here, immediately after signing in — before you even reach the dashboard. Enter it now. By the time we reach the Approve step below, this session will already be fully verified, so clicking Approve will go straight through without asking again.

[NAVIGATE] I'll move to Write-offs & Adjustments.

[EXPLAIN] Not every stock discrepancy is a request, a receipt or a transfer. Sometimes stock simply needs to be corrected — damage, a stock count that doesn't match, or a similar reason. That's what this section is for.

[DEMONSTRATE] I'm going to raise an adjustment against the demo product now, selecting a reason and a quantity. Notice that raising one, on its own, doesn't change any stock yet either — it goes into a pending state, exactly like a requisition does, until someone with the authority to approve it reviews it.

[IMPORTANT / BACKUP] Approving this is one of the most sensitive actions in the entire system, because it directly changes your stock position with no second person double-checking it afterwards. That's why the system requires an extra step here.

[DEMONSTRATE] I'll open the pending adjustment now and click Approve.

[EXPLAIN] Notice that went through immediately, with no extra prompt on this screen — because this account already proved its identity with a verification code from an authenticator app the moment we signed in, before we could even reach the dashboard. That verification isn't required just to log in and raise a request; it's specifically required for an account that's allowed to approve — the single most sensitive action in the system, where stock actually changes with no second person double-checking it afterwards. Only an already-verified, 2FA-enrolled session was allowed to complete that approval.

PART 16 — MOVEMENT / AUDIT HISTORY

[NAVIGATE] I'll move now to the history section, so we can look back at everything we've actually just done.

[EXPLAIN] One of the most important things about an inventory system isn't just knowing where stock is right now — it's knowing what happened to it, and who was responsible.

[DEMONSTRATE] Here you can see a running record of every action — who performed it, what it was, and exactly when it happened. This record can't be edited or deleted afterwards, which means it's a genuine, permanent history, not just a status that could quietly be changed later. If I scroll through, you can actually see the receipt, the requisition approval, the acceptance, the transfer and the adjustment we've just walked through, each one attributed to the account that performed it.

PART 17 — REPORTS

[NAVIGATE] Now that we've built up some real activity, I'll move into Reports, to show you how all of that comes together for management.

[EXPLAIN] There's a full set of standard reports here, and each one is built to answer a specific business question — not just to show raw data.

Stock valuation — how much inventory are we currently holding, and what is it worth?

Low stock / reorder suggestions — which items need attention because they've dropped below their reorder point?

Dormant stock — which items haven't moved and may need review?

Requisition summary — what has each department requested, and where does it stand?

Pick list — what's approved and ready to be physically picked?

Purchase order summary and Open purchase orders — what have we ordered, and what's still outstanding?

Stock movement history and Receiving history — the full transaction trail behind every number.

Adjustment reason summary — how many corrections have been raised, and why.

There are a few more besides — including store-level, department-level and supplier-level summaries, and a roll-up of movement types.

[DEMONSTRATE] Every one of these can be exported, so this information isn't locked inside the system — I'll point to the export/CSV option on this report as an example.

[IMPORTANT / BACKUP] This next part is specifically for the requirement you've raised about repair costing. Read it carefully rather than skipping past it.

[EXPLAIN] We've now followed one material from the original request, through Stores approval, to the Engineer, and finally to consumption. The natural next step, from a management point of view, is a report that answers one specific question: for this repair, what materials were consumed, and what did they cost in total?

[CLIENT CONFIRMATION] I want to be straightforward with you: that Repair Cost Report doesn't exist yet. It's not that the information is missing forever — every piece it would need is information we've already shown you today: the product, its catalogue cost, the quantity issued, and the quantity used. What's missing is the one connecting thread we've talked about throughout this demonstration: the repair reference itself, captured at the request and carried through to consumption. Once that reference exists, this report becomes straightforward to build: filtered to one repair, it would show the repair or reference, the site or asset it relates to, every material used against it, the quantities, the material costs, and the total material cost for that repair. I'd like to confirm with you now exactly which of those columns matter most to you, so we build the report around what you'll actually use, rather than guessing.

PART 18 — STOCK VALUATION

[NAVIGATE] I want to spend a moment specifically on Stock Valuation, because it directly reflects everything we've done today.

[EXPLAIN] We received stock into the store earlier. Some of that stock was then requested, approved and issued. This report shows you what all of that leaves you holding, and what it's worth, based on the average cost of each item — giving management a real financial view of inventory, not just a unit count.

[DEMONSTRATE] I'll point to the value for the demo product and connect it back to the earlier receipt.

PART 19 — LOW STOCK / DORMANT STOCK

[NAVIGATE] Two more reports worth highlighting for day-to-day management — I'll show you both briefly.

[EXPLAIN] Low stock tells you immediately which items have fallen below the level you've decided is acceptable, so replenishment can be planned before it becomes a problem. Dormant stock does the opposite job — it flags items that simply haven't moved, which is often just as useful to know, because it can point to stock that's no longer needed or has been forgotten.

PART 20 — ADMINISTRATION / OVERSIGHT, AND THE FULL ROLE PICTURE

[NAVIGATE] Finally, I'll show you how the organisation maintains control over who can do what, and go through the specific roles you've raised with us.

[EXPLAIN] Admin manages every user account, assigns each person their role, and can see exactly what each role is able to do. Different roles genuinely see different things and can perform different actions — you'll have noticed throughout this walkthrough that the Engineer's account couldn't do what the Admin account could, and that's intentional. Responsibility is matched to role, on purpose, throughout the whole system.

[DEMONSTRATE] I'll open the Users page briefly, without changing anything on a real account, so you can see where roles are assigned.

[EXPLAIN] Two roles you've raised with us are already fully configured today, with their own permissions and their own view of the system: Stores Clerk, who handles day-to-day receiving, transfers and purchase orders but cannot raise an adjustment; and the two Team Leader roles, Mechanical and Electrical, who each get oversight of their own team's requisitions and reporting, without store-management responsibility. I could switch into either of those accounts to show you their view directly, if you'd like to see it now.

[EXPLAIN] If I were showing you a Team Leader account, the way I'd introduce it is: I'm looking at this from the Mechanical Team Leader's perspective now. The purpose of this role isn't to perform Stores operations — it's to give the right level of oversight over the Mechanical team's requests and stock activity, scoped to their own team rather than the whole business.

[CLIENT CONFIRMATION] The one role you've raised that isn't configured as its own separate role yet is Stores Assistant. Today, Stores Clerk is the closest existing equivalent, and it already covers day-to-day receiving, transfers and purchase orders. I want to confirm with you directly: does Stores Assistant need to be its own distinct role with different permissions to Stores Clerk, or is Stores Clerk, under a different name, actually what you had in mind?

[CLIENT CONFIRMATION] And more broadly, across all of these roles — Stores Clerk, Stores Assistant, Mechanical Team Leader and Electrical Team Leader — I'd like to walk through the exact permissions with you at a follow-up session: what each one should specifically be able to see and do, so we can confirm the permission list role by role rather than leaving any of it assumed.

[EXPLAIN] The last thing I want to revisit is the Engineer's own dashboard, because it's one of your requirements and it's already real, not just planned. When we signed in as the Engineer earlier, the stock view on their Overview opened directly on their own station's stock, not the whole store — the system already tailors that first view to the person logged in, so an Engineer sees what belongs to them first, rather than having to filter it out of everyone else's. The reminder we showed you earlier is part of that same picture. What we haven't built yet is a separate set of dedicated summary cards beyond that — if there are specific numbers you want an Engineer to see the moment they log in, beyond their own stock and their reminders, I'd like to know what those are.

Closing

To bring everything together: what you've seen today is that Cobro IMS isn't simply a list of stock. It follows the actual journey of that stock through your organisation — from the moment it arrives in Stores, through requests, approvals and dispatches, out to the people who need it, and back again if it isn't used — and every one of those steps is recorded automatically, permanently, and attributed to the person responsible for it.

I also want to be honest about where we are with the specific points you've raised with us. The foundation all of that sits on is already built and working: the product catalogue, the approval and reservation model, role-based access, the audit trail, and reporting. What we've confirmed today as the next piece of work is the thread that runs through all of it for a repair specifically — how a repair is identified, how that reference travels with the material from request through to consumption, and how it rolls up into a cost report you can hand to management. None of that requires rethinking what you've already seen today — it builds directly on top of it.

I'm happy to answer any questions, or go back into any part of this in more depth.

CLIENT REQUIREMENTS — PRESENTATION COVERAGE CHECK

Internal, presenter-only. Not for the client. Every requirement raised in previous meetings, where it's addressed in this script, and its honest status.

#	Requirement	Addressed in	Status
1	For Use / For Repair option on the requisition	Part 8	Requires Client Confirmation
2	Repair/job description capture	Part 8	Requires Client Confirmation
3	Link repair to a specific site/asset (e.g. No. 2 Machine)	Part 8	Requires Client Confirmation
4	Material cost automatically from Product Catalogue	Part 4, Part 8	Requires Client Confirmation — catalogue cost is real and Admin-controlled; the requisition form doesn't pull it in yet
5	Repair/use purpose visible to Stores on the requisition	Part 9	Requires Client Confirmation
6	Repair reference stays linked through approve & issue	Part 11	Requires Client Confirmation
7	Consumed materials identified against the repair	Part 14	Requires Client Confirmation
8	Repair Cost Report (repair, materials, cost, total)	Part 17	Requires Client Confirmation — not built; every underlying data point exists once #1–7 are resolved
9	Reserved stock correctly reflected for Stores	Part 9	Demonstrated — confirmed working (on-hand vs. reserved)
10	Roles: Stores Clerk, Stores Assistant, Mechanical TL, Electrical TL	Role Overview, Part 20	Partially Demonstrated — the first 3 are configured with real permissions; Stores Assistant does not exist as a distinct role
11	Permissions and UI for those roles	Part 20	Partially Demonstrated / Requires Client Confirmation — existing 3 roles' permissions are real and shown; exact scope for all 4 needs a role-by-role confirmation pass
12	Engineer-specific dashboard / stock cards	Part 3, Part 20	Partially Demonstrated — the Overview genuinely opens on the Engineer's own station by role; no separate dedicated summary-card UI exists beyond that
13	Use/return reminders for Engineers	Part 13	Demonstrated — real, live, in the notification bell (14-day held-stock threshold); exact policy (frequency/escalation) still open
14	Monthly Engineer stock offer/return workflow	Part 13	Requires Client Confirmation — not built; only the standing reminder above exists today
15	Confirm final Store / Facility / Workshop names	Part 5	Requires Client Confirmation
16	Confirm official repair identification/reference	Part 8	Requires Client Confirmation

Every requirement above has a spoken [CLIENT CONFIRMATION] moment at its natural point in the walkthrough — none are read out as a checklist to the client. The 12 confirmation questions requested for this section map onto rows 1–8, 10–11, and 14–16 above (roles 10/11 together cover both the role-permission questions).

Self-check performed before finalising this script: every client requirement listed has a home in the walkthrough; no standalone silent action line remains anywhere (every navigation, click, selection, entry, scan, filter, submission, approval and role switch is spoken, in a single paragraph, alongside its reason); nothing was invented — every [CLIENT CONFIRMATION] box corresponds to a feature independently confirmed absent from the current source code (src/lib/domain/inventory.ts, sales-order-form.tsx, reports/page.tsx, permissions.ts) immediately before writing this document; no code, architecture or technical behaviour was changed or proposed.
